INTRODUCTION

The complexity of neutron transport in terms of space, time, and neutron energy dependence is well recognized. Through the years, there have been many attempts to utilize various parameters to characterize a neutron system to help nuclear engineers to understand various applications. Parameters such as $k_{\rm eff}$, neutron spectrum, average energy of neutrons causing fissions, and others are used to size up the types of the problems in a particular application. From a neutron physics viewpoint, not all the parameters used are of the same usefulness.

DESCRIPTION OF THE WORK

It is interesting to point out that under the density law transformation [1,2], some parameters offer better physics insight than others. For example, parameters such as the number of mean free paths, nonleakage fraction, and surface mass density, are invariant under the density law transformation. Actually, the transport equation and the diffusion equation are invariant under the density law transformation. This means if we use parameters, which are invariant under the density law, the neutron physics is the same for various systems with the same parameter value. The density law is an inherent property of the neutron transport process. Given the complexity of the neutron transport process, the density law gives us a certain physics insight that is very helpful for practitioners in the criticality safety field. With this in mind, this paper presents another way of looking at fissile systems by using parameters that are invariant under the density law.

RESULTS

Use of the Nonleakage Fraction (or the Leakage Parameter)

In reactor physics and in criticality applications, various approaches are used to dissect a problem into

the geometry and material perspectives. For example, we use B_g^2 for geometric buckling and B_m^2 for material buckling in a way to help us understand what parameters are in the material side and what parameters in the geometry side and how they are related to criticality assessment. As a matter of fact, this approach is very powerful in developing many hand calculation methods such as the J. Thomas's limiting surface density method [3].

In an infinite medium problem, there is no neutron leakage. A parameter such as $K_{\rm inf}$ and its associated four factor formula are used to explain neutron transport for this type of problems. For a finite neutron system, the neutron leakage plays an important role. For example, it is customary to represent the neutron reproduction factor as follows:

$$K_{eff} = K_{inf} * (nonleakage Fraction)$$

= $K_{inf} / (1+M^2B^2)$

where M² may be interpreted as the migration area and B² as the geometric buckling under the modified one group model. Although we illustrate the concept with a modified one group model, the overall concept of nonleakage fraction is independent of the model used as the nonleakage fraction may be obtained by various methods including the Monte Carlo method.

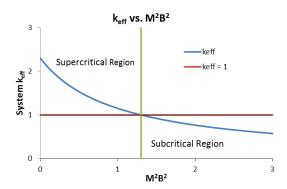

Figure 1. k_{eff} as a function of M^2B^2 .

Figure 1 shows that the use of M^2B^2 as a parameter will yield a few additional physics insights than just the k_{eff} value. Thus,

$$M^2B^2 = K_{inf} - 1$$
 \rightarrow Critical $M^2B^2 < K_{inf} - 1$ \rightarrow Supercritical $M^2B^2 > K_{inf} - 1$ \rightarrow Subcritical

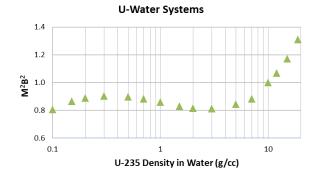

Figure 2. M^2B^2 as a function of the U-235 density in 235 U-Water Systems.

Figure 2 shows a M²B² plot against uranium density at critical conditions. For example, the maximum value of K_{inf} of the water moderated uranium systems is about 2.3 at full U-235 density and hence the same systems with M²B² greater than 1.3 are subcritical in general as a first order approximation. This corresponds to a nonleakage fraction less than 0.43 for the subcritical region. Thus, the nonleakage fraction in general or M²B² under the modified one group model provides us with a good parameter to understand the criticality issue. It is noted that there are many water moderated uranium systems with the same M²B² value (smaller M² and bigger B² or larger M^2 and smaller B^2) which should give the same K_{eff} value. The M²B² parameter gives us additional insights for various systems with the same fissile material regarding neutron leakage.

Use of Number of Neutron Mean Free Paths

In applying the same concept, the use of number of neutron mean free paths to assess criticality safety appears to offer the same benefits. The number of neutron mean free paths for a system is invariant under the density law transformation. For systems with the same material composition, the same

number of the mean free path offers very similar neutron physics. Obviously, the length of a neutron mean free path of a system is a material side property but the number of neutron mean free paths of a system depends also upon the geometry side of the system. Of course, the length of mean free path depends upon reaction types and also is neutron energy dependent. Because of the neutron transport process, the density law gives us certain advantages in using the number of the mean free paths to assess criticality issues. A criticality safety engineer may want to utilize this parameter in addition to other parameters such as K_{eff}, leakage fraction etc., as the tools in the tool box for criticality safety assessment.

CONCLUSIONS

The density law offers a few physics insights to the neutron transport process. We have illustrated that the use of parameters which are invariant under the density law offers another interesting way of looking at criticality safety issues. Obviously, because of the complexity of neutron transport process, there is no single silver bullet that resolves all criticality issues. Nevertheless, the use of the number of mean free paths or nonleakage fraction or other parameters from the density law perspective do offer us another venue for helping practitioners deal with never ending varieties of criticality safety applications.
